Our motivation for the study of fullerenes - structural properties of fullerenes

A 3 1 A 3 1

-21

The question of finding or proving existence of Hamilton (or long) cycles or paths in graphs has long been an active area of research.

- Hamilton cycle = simple cycle traversing every vertex
- Hamilton path = simple path traversing every vertex

Two particular instances of this general problem are:

- Hamilton cycles/paths in vertex-transitive graphs (Lovasz,'69)
- Hamilton cycles in fullerenes a special case of one of Barnette's conjectures.

Does every connected vertex-transitive graph have a Hamilton path?

A graph X = (V, E) is vertex-transitive if for any pair of vertices u, v there exists an automorphism α such that $\alpha(u) = v$.

4

Given a group G and a subset S of $G \setminus \{1\}$ such that $S = S^{-1}$, the Cayley graph Cay(G, S) has vertex set G and edges of the form

$$\{g,gs\} \ \text{ for all } g\in G \text{ and } s\in S.$$

- Every Cayley graph is vertex-transitive.
- There exist vertex-transitive graphs that are not Cayley.

Conjecture

Every connected Cayley graph has a Hamilton cycle.

A 3 1 A 3 1

Example

Is not Cayley

Is Cayley

● ▶ ★ 臣 ▶ ★ 臣 ▶

æ

Given a group G and a generating set S of G, the Cayley graph Cay(G, S) is cubic iff |S| = 3 and

•
$$S = \{a, b, c \mid a^2 = b^2 = c^2 = 1\}$$
 or

•
$$S = \{a, b, b^{-1} \mid a^2 = b^s = 1\}.$$

★ E ► ★ E ►

-2

Theorem (Glover, Marušič, 2007)

Let $s \ge 3$ be an integer, let G be a group with a presentation $G = \langle a, b \mid a^2 = b^s = (ab)^3 = 1, ect. \rangle$, and let $S = \{a, b, b^{-1}\}$. Then

- if |G| ≡ 2(mod 4) the Cayley graph Cay(G, S) has a Hamilton cycle, and
- if |G| ≡ 0(mod 4) the Cayley graph Cay(G, S) has a cycle missing out only two adjacent vertices and therefore a Hamilton path.

Theorem (Glover, KK, Marušič, 2009)

If $s \equiv 0 \pmod{4}$ or s is odd then the Cayley graph Cay(G, S) has a Hamilton cycle.

・ 同 ト ・ ヨ ト ・ ヨ ト

Each Cayley graph we study has a canonical Cayley map given by an embedding of the Cayley graph $X = Cay(G, \{a, b, b^{-1}\})$ of the (2, s, 3)-presentation of a group $G = \langle a, b | a^2 = 1, b^s = 1, (ab)^3 = 1, etc. \rangle$ in the closed orientable surface of genus

$$1+(s-6)\frac{|G|}{12s}$$

with faces $\frac{|G|}{s}$ disjoint *s*-gons and $\frac{|G|}{3}$ hexagons.

How is this done?

By finding a tree of faces in this canonical Cayley map whose boundary encompasses all vertices of the graph.

A tree of faces

э

Hamilton cycle in Buckminsterfullerene

The Buckminsterfullerene is one of only two vertex-transitive fullerenes (the other is the Dodecahedron) and it is in fact a Cayley graph of A_5 .

Essential ingredient in this Hamiltonian tree of faces method is the concept of cyclic edge-connectivity and to use a similar method in the context of fullerenes cyclic edge-connectivity of fullerenes need to be studied.

Cyclic edge connectivity of fullerenes

(B)

-2

Cycle-separating subset

A subset $F \subseteq E(X)$ of edges of X is said to be cycle-separating (or cyclic-edge cutset) if X - F is disconnected and at least two of its components contain cycles. A cycle-separating subset F of size k is trivial if at least one of the resulting components induces a single k-cycle.

Cycle-separating subset

A subset $F \subseteq E(X)$ of edges of X is said to be cycle-separating (or cyclic-edge cutset) if X - F is disconnected and at least two of its components contain cycles. A cycle-separating subset F of size k is trivial if at least one of the resulting components induces a single k-cycle.

Cyclically k-edge-connected graphs

A graph X is cyclically k-edge-connected, if no set of fewer than k edges is cycle-separating in X.

글 에 에 글 어

Open problem (Marušič, 1981)

Is it true that a vertex-transitive digraph contains a semiregular automorphism?

In the context of vertex-transitive graphs the existence of semiregular automorphisms helps proving the existence of Hamilton paths/cycles for some classes of such graphs.

It seems reasonable to expect that methods similar to those used for finding Hamilton paths/cycles in vertex-transitive graphs could be applied, at least in some cases, to fullerenes as well.

Motivated by this problem we recently characterized fullerenes with regards to the existence of semiregular automorphisms in their automorphism groups.

Theorem (Janežič, Marušič, KK, 2010)

Let F be a fullerene with non-trivial automorphism group. Then either F admits a semiregular automorphism or $Aut(F) \cong \mathbb{Z}_2$, \mathbb{Z}_3 or S_3 .

- The automorphism group Aut(F) of a fullerene F is a subgroup of a {2,3,5}-group (Fowler, Manolopoulos, Redmond and Ryan, 1993).
- Let F be a fullerene admitting an automorphism α ∈ Aut(F) of order 5. Then α is a semiregular automorphism of F.
- Leapfrog transformation enables us to construct an infinite family of fullerenes with a prescribed non-trivial automorphism group and having a semiregular automorphism.
- On the other hand, there are also infinitely many fullerenes having non-trivial automorphism groups without semiregular automorphisms.
